" Missing Patch The following patch files have not been applied because they are not attached to a valid bug report:The present invention relates to rotary offset printing machines of the type where the paper sheet is guided between the rollers and the plate cylinder. In particular, the present invention relates to a sheet path bypass control mechanism which permits selective displacement of the paper sheet from a first path leading to the rollers, to a second path, the paper sheet following the curve on the plate cylinder. Prior to the present invention, three different bypass mechanisms for plate rollers in printing machines were known. First, a mechanical bypass adjustment mechanism was available, providing the paper sheet to the rollers by extending a suitable side edge of the paper sheet to engage a bypass control bar, displacing the bar in a direction opposite to the paper sheet away from the rollers. The bar engages a plurality of clamping members which, in turn, engage the edges of the paper sheet to hold it in position in the path of the rollers. The bar is moved in response to manual operation from one end to the other, by means of an actuator knob which is attached to the bar. The amount of bar displacement is set by means of a suitable lever mechanism. The second prior art bypass system consists of the provision of a scissors-type linkage mounted on a suitable carriage. The scissors-type linkage engages the paper sheet, displacing it away from the rollers. The scissors-type linkage is actuated by a suitable actuator mechanism. The third prior art bypass system consists of a pivoted carriage having a slot through which the paper sheet extends. The slots are sized to receive the edges of the paper sheet, and the carriage is moved by means of a mechanism located at one end of the paper path to cause the paper sheet to extend through the slot and then into the path of the rollers. The first two prior art bypass systems suffer from the disadvantage that, in order to disengage the paper sheet from the roller path, the mechanism is actuated to lower a portion of the bar, or to actuate the scissors-type linkage, or to move the carriage. In each case, a force must be applied to the part of the bypass mechanism which is moved in order to disengage the paper sheet from the roller path. The force required increases as the weight of the paper sheet increases, since
